

## United States Life Tables, 2000

by Elizabeth Arias, Ph.D., Division of Vital Statistics

### Abstract

This report presents period life tables for the United States based on age-specific death rates in 2000. Data used to prepare these life tables are 2000 final mortality statistics; July 1, 2000, population estimates based on the 1990 decennial census; and data from the Medicare program. Presented are complete life tables by age, race, and sex. In 2000 the overall expectation of life at birth was 76.9 years, representing an increase of 0.2 years from life expectancy in 1999. Between 1999 and 2000, life expectancy increased for both males and females and for both the white and black populations. Life expectancy increased by 0.4 years for black males (from 67.8 to 68.2) and by 0.2 years for white males (from 74.6 to 74.8). It increased by 0.2 years for black females (from 74.7 to 74.9) and by 0.1 year for white females (from 79.9 to 80.0).

### Introduction

There are two types of life tables—the cohort (or generation) life table and the period (or current) life table. The cohort life table presents the mortality experience of a particular birth cohort, all persons born in the year 1900, for example, from the moment of birth through consecutive ages in successive calendar years. Based on age-specific death rates observed through consecutive calendar years, the cohort life table reflects the mortality experience of an actual cohort from birth until no lives remain in the group. To prepare just a single complete cohort life table requires data over many years. It is usually not feasible to construct cohort life tables entirely on the basis of observed data for real cohorts due to data unavailability or incompleteness (1). For example, a life table representation of the mortality experience of a cohort of persons born in 1970 would require the use of data projection techniques to estimate deaths into the future (2,3).

Unlike the cohort life table, the period life table does not represent the mortality experience of an actual birth cohort. Rather, the period life table presents what would happen to a hypothetical (or synthetic) cohort if it experienced throughout its entire life the mortality conditions

of a particular period in time. Thus, for example, a period life table for 2000 assumes a hypothetical cohort subject throughout its lifetime to the age-specific death rates prevailing for the actual population in 2000. The period life table may thus be characterized as rendering a “snapshot” of current mortality experience, and shows the long-range implications of a set of age-specific death rates that prevailed in a given year. In this report the term “life table” refers only to the period life table and not to the cohort life table.

### Data and Methods

The data used to prepare the U.S. life tables for 2000 are final numbers of deaths for the year 2000; postcensal population estimates for the year 2000; and data from the Medicare program prepared by the Health Care Financing Administration. Population estimates are prepared by the U.S. Census Bureau. They are based on the 1990 decennial census because detailed populations from the 2000 census were not available when this report was prepared. A comparison of 1990 census based estimates and summary 2000 census results show differences for some ethnic and race groups. These differences could result in the underestimation or overestimation of life expectancy (see [Technical Notes](#)). Once population estimates based on the 2000 census are available, we will publish another report presenting revised life expectancy estimates. Data from the Medicare program are used to calculate probabilities of dying for ages over 85 years (see [Technical Notes](#)).

Life tables can be classified in two ways according to the length of the age interval in which data are presented. A complete life table

---

### Acknowledgments

This report was prepared in the Division of Vital Statistics under the general direction of Robert N. Anderson, Lead Statistician, and James A. Weed, Acting Chief, Mortality Statistics Branch. Registration Methods Staff and the Data Acquisition and Evaluation Branch provided consultation to State vital statistics offices regarding the collection of the death certificate data on which this report is based. This report was edited by Demarius V. Miller, typeset by Jacqueline M. Davis, and graphics produced by Jarmila Ogburn of the Publications Branch, Division of Data Services.

---

contains data for every single year of age. An abridged life table typically contains data by 5- or 10-year age intervals. A complete life table, of course, can be easily aggregated into 5- or 10-year age groups ( see [Technical Notes](#) for instructions on how to do this). Other than the decennial life tables, U.S. life tables based on data prior to 1997 are abridged life tables constructed by reference to a “standard” table (4). The 2000 U.S. life tables are complete life tables calculated using a method implemented with the 1997 life tables and are similar to the U.S. Decennial Life Tables (5,6). See [Technical Notes](#) for more information on the method used to construct the life tables in this report.

**Expectation of life**—The most frequently used life table statistic is life expectancy ( $e_x$ ), which is the average number of years of life remaining for persons who have attained a given age ( $x$ ). Life expectancy and other life table values for each age in 2000 are shown for the total population and by race and sex in [tables 1–9](#). Life expectancy is summarized by age, race, and sex in [table A](#).

Life expectancy at birth ( $e_0$ ) for 2000 for the total population was 76.9 years. This represents the average number of years that the members of the hypothetical life table cohort may expect to live at the time of birth ([table A](#)).

**Survivors to specified ages**—Another way of assessing the longevity of the synthetic life table cohort is by determining the proportion who survive to specified ages. The  $l_x$  column of the life table provides the data for computing the proportion. [Table B](#) summarizes the number of survivors by age, race, and sex. To illustrate, 51,037 persons out of the original 2000 synthetic life table cohort of 100,000 (or 51.0 percent) were alive at exact age 80. In other words, the probability that a person will survive from birth to age 80, given 2000 age-specific mortality, is 51 percent. Probabilities of survival can be calculated at any age by simply dividing the number of survivors at the terminal age by the number at the beginning age. For example, to calculate the probability of surviving from age 20 to age 85, one would divide the number of survivors at age 85 (34,959) by the number of survivors at age 20 (98,654), which results in a 35.4 percent probability of survival.

### Explanation of the columns of the life table

**Column 1—Age ( $x$  to  $x + 1$ )**—This column shows the age interval between the two exact ages indicated. For instance, “20–21” means the 1-year interval between the 20th and 21st birthdays.

**Column 2—Probability of dying ( $q_x$ )**—This column shows the probability of dying between ages  $x$  to  $x+1$ . For example, for males in the age interval 20–21 years, the probability of dying is .001295 ([table 2](#)). The “probability of dying” column forms the basis of the life table; all subsequent columns are derived from it.

**Column 3—Number surviving ( $l_x$ )**—This column shows the number of persons from the original synthetic cohort of 100,000 live births, who survive to the beginning of each age interval. The  $l_x$  values are computed from the  $q_x$  values, which are successively applied to the remainder of the original 100,000 persons still alive at the beginning of each age interval. Thus out of 100,000 female babies born alive, 99,376 will complete the first year of life and enter the second; 99,189 will reach age 10; 98,909 will reach age 20; and 42,145 will live to age 85 ([table 3](#)).

**Column 4—Number dying ( $d_x$ )**—This column shows the number dying in each successive age interval out of the original 100,000 live births. For example, out of 100,000 males born alive, 759 will die in the first year of life; 127 between ages 20 and 21; and 864 will die after reaching age 100 ([table 2](#)). Each figure in column 4 is the difference between two successive figures in column 3.

**Column 5—Person-years lived ( $L_x$ )**—This column shows the number of person-years lived by the synthetic life table cohort within an age interval  $x$  to  $x+1$ . Each figure in column 5 represents the total time (in years) lived between two indicated birthdays by all those reaching the earlier birthday. Thus, the figure 98,349 for males in the age interval 20–21 is the total number of years lived between the 20th and 21st birthdays by the 98,413 (column 3) males who reached their 20th birthday out of 100,000 males born alive ([table 2](#)).

**Column 6—Total number of person-years lived ( $T_x$ )**—This column shows the total number of person-years that would be lived after the

100	1,781	864	2,479	1,618	773	2,244	1,388	754	1,831

beginning of the age interval  $x$  to  $x+1$  by the synthetic life table cohort. For example, the figure 5,434,563 is the total number of years lived after attaining age 20 by the 98,413 males reaching that age (table 2).

**Column 7—Expectation of life ( $e_x$ )**—The expectation of life at any given age is the average number of years remaining to be lived by those surviving to that age on the basis of a given set of age-specific rates of dying. It is derived by dividing the total person-years that would be lived above age  $x$  by the number of persons who survived to that age interval ( $T_x/l_x$ ). Thus, the average remaining lifetime for males who reach age 20 is 55.2 years (5,434,563 divided by 98,413) (table 2).

## Results

### Life expectancy in the United States

Tables 1–9 show complete life tables by race (white and black) and sex for 2000. Tables A and B summarize life expectancy and survival by age, race, and sex. Life expectancy at birth for 2000 represents the average number of years that a group of infants would live if the infants were to experience throughout life the age-specific death rates prevailing in 2000. In 2000 life expectancy at birth was 76.9 years, increasing by 0.2 years from 76.7 years in 1999. This increase is typical of the average yearly changes that occurred during the last 25 years in the United States. Throughout the 20th century, the trend in U.S. life expectancy was one of gradual improvement (7).

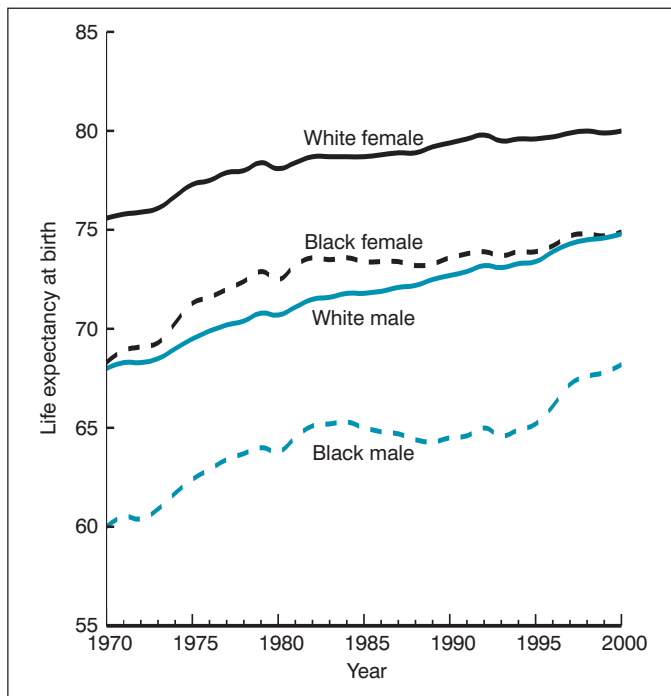

Life expectancy was 74.1 years for males, increasing by 0.2 years from 73.9 years in 1999. Life expectancy for females in 2000 was 79.5 years, increasing by 0.1 year from 79.4 years in 1999. The increase in life expectancy between 1999 and 2000 for females was primarily the result of decreases in mortality due to diseases of the heart, cancer, perinatal conditions, and chronic lower respiratory diseases. Increases in life expectancy took place despite increases in mortality due to Alzheimer's disease, kidney disease, and pneumonitis due to solids and liquids. For males, life expectancy increased as a result of decreases

in mortality from heart disease, stroke, cancer, and lower respiratory diseases, which were partly offset by increases in mortality due to kidney disease, Alzheimer's disease, viral hepatitis, and pneumonitis due to solids and liquids.

The difference in life expectancy between the sexes was 5.4 years in 2000, a slight narrowing from the difference (5.5) in the previous year. From 1900 to 1975, the difference in life expectancy between the sexes increased from 2.8 years to 7.8 years. The increasing gap during these years is attributed to increases in male mortality due to ischemic heart disease and lung cancer, both of which increased largely as the result of men's early and widespread adoption of cigarette smoking (7,8). Since 1979, the difference in life expectancy between the sexes has narrowed from 7.8 years to 5.4 years, reflecting proportionately greater increases in lung cancer mortality for women than for men and proportionately larger decreases in heart disease mortality among men (7,8).

Between 1999 and 2000, life expectancy for the black population rose 0.3 years to 71.7 years. For the white population life expectancy rose by 0.1 year to 77.4 years. The difference in life expectancy between the white and black populations was 5.7 years in 2000, returning to its record low level first observed in 1982. The white-black difference in life expectancy narrowed from 15.8 years in 1900 to 5.7 years in 1982, but increased to 7.1 years in 1993 before declining from 1994 (7.0 years) to 2000 (5.7 years). The increase in the gap from 1983 to 1993 was largely the result of increases in mortality among the black male population due to HIV infection and homicide (7,9).

Among the four race-sex groups (figure 1), white females continued to have the highest life expectancy at birth (80.0 years), followed by black females (74.9 years), white males (74.8 years), and black males (68.2 years). Between 1999 and 2000, life expectancy increased 0.4 years for black males (from 67.8 in 1999 to 68.2 in 2000). Black males experienced an unprecedented decline in life expectancy every year for 1984–89 (8), but annual increases in 1990–92 and 1994–2000. From 1999 to 2000, life expectancy for black females increased from

**Figure 1. Life expectancy at birth by race and sex: 1970–2000**

74.7 years to 74.9 years, an increase of 0.2 years. Life expectancy for white males rose 0.2 years, from 74.6 years in 1999 to 74.8 years in 2000. White female life expectancy increased during the same period by 0.1 year from 79.9 to 80.0 years. Overall, gains in life expectancy between 1980 and 2000 were 4.4 years for black males, 4.1 years for white males, 2.4 years for black females, and 1.9 years for white females (table 12).

The 2000 life table may be used to compare life expectancy at any age from birth onward. On the basis of mortality experienced in 2000, a person aged 65 years could expect to live an average of 17.9 more years for a total of 82.9 years, and a person age 100 years could expect to live an additional 2.6 years on average (table A). Life expectancy at 100 years of age, particularly for the black population, should be interpreted with caution as these figures may be affected somewhat by age misreporting (5,10,11).

### Survivorship in the United States

Table B summarizes the number of survivors out of 100,000 persons born alive ( $l_x$ ) by age, race, and sex. Table 10 shows trends in survivorship from 1900 to 2000. In 2000, 99.3 percent of all infants born in the United States survived the first year of life. In contrast, only 87.6 percent of infants born in 1900 survived the first year. Fifty-one percent of the 2000 synthetic life table cohort survived to age 80, and about 1.8 percent survived to age 100. In 1900 the median age at death was 58 and only 0.03 percent survived to age 100.

Among the four race-sex groups (figure 2, table B), white females have the highest median age at death with 50 percent surviving to age 83. Of the original hypothetical cohort of 100,000 infant white females, 99.0 percent survive to age 20, 87.4 percent survive to age 65, and 43.1 percent survive to age 85. For white males and black females, the pattern of survival by age is similar. These groups have approximately

the same median age at death of 78 years. However, white males have slightly higher survival rates than black females at the younger ages with 98.6 percent surviving to age 20 and 79.4 percent surviving to age 65 compared with 98.1 percent and 78.0 percent, respectively, for black females. At the older ages, in contrast, black female survival surpasses white male survival. At age 85, white male survival is 28.1 percent compared with 31.4 percent for black females. This crossover, which occurs at about age 72, is clearly shown in figure 2. The median age at death for black males is 72 years, 11 years less than that for white females; 97.3 percent of black males survive to age 20, 64.0 percent to age 65, and 17.4 percent to age 85. By age 100, there is very little difference between the white and black populations in terms of survival. Somewhat less than 1 percent of white and black males and about 2 percent of white and black females survive to age 100.

Plotting the percent surviving by age for the periods 1900–1902, 1949–51, and 2000 shows an increasingly “rectangular” survival curve (figure 3). That is, the survival curve has become increasingly flat in response to progressively lower mortality, particularly at the younger ages, and increasingly vertical at the older ages. The survival curve for 1900–1902 shows a rapid decline in survival in the first few years of life and a relatively steady decline thereafter. In contrast, the survival curve for 2000 is nearly flat until about age 50 after which the decline in survival becomes more rapid. Improvements in survival between 1900–1902 and 1949–51 occurred at all ages, although the largest improvements were among the younger population. Between 1949–51 and 2000, improvements occurred primarily for the older population.

Figure 2. Percent surviving by age, race, and sex: United States, 2000

Figure 3. Percent surviving by age: Death-registration States, 1900–1902, and United States, 1949–51 and 2000

## List of Detailed Tables

1. Life table for the total population: United States, 2000 . . . . .	7
2. Life table for males: United States, 2000 . . . . .	9
3. Life table for females: United States, 2000 . . . . .	11
4. Life table for the white population: United States, 2000. . . . .	13
5. Life table for white males: United States, 2000 . . . . .	15
6. Life table for white females: United States, 2000 . . . . .	17
7. Life table for the black population: United States, 2000. . . . .	19
8. Life table for black males: United States, 2000 . . . . .	21
9. Life table for black females: United States, 2000 . . . . .	23
10. Survivorship by age, race, and sex: Death-registration States, 1900–1902 to 1919–21, and United States, 1929–31 to 2000 . . . . .	25
11. Life expectancy by age, race, and sex: Death-registration States, 1900–1902 to 1919–21, and United States, 1929–31 to 2000 . . . . .	29
12. Estimated life expectancy at birth in years, by race and sex: Death-registration States, 1900–28, and United States, 1929–2000 . . . . .	33

Table 1. Life table for the total population: United States, 2000

Age	Probability of dying between ages $x$ to $x+1$	Number surviving to age $x$	Number dying between ages $x$ to $x+1$	Person-years lived between ages $x$ to $x+1$	Total number of person-years lived above age $x$	Expectation of life at age $x$
	$q_x$	$l_x$	$d_x$	$L_x$	$T_x$	$e_x$
0-1	0.006930	100,000	693	99,392	7,686,810	76.9
1-2	0.000517	99,307	51	99,281	7,587,418	76.4

**Table 10. Survivorship by age, race, and sex: Death-registration States, 1900–1902 to 1919–21, and United States, 1929–31 to 2000**

[Alaska and Hawaii included beginning in 1959. For decennial periods prior to 1929–31, data are for groups of registration States as follows: 1900–1902 and 1909–11, 10 States and the District of Columbia; 1919–21, 34 States and the District of Columbia. Beginning 1970 excludes deaths of nonresidents of the United States; see Technical Notes]

Age, race, and sex	Number of survivors out of 100,000 born alive ( <i>L<sub>x</sub></i> )										
	2000	1989–91	1979–81	1969–71	1959–61	1949–51	1939–41	1929–31	1919–21	1909–11	1900–1902

See footnote at end of table.

**Table 10. Survivorship by age, race, and sex: Death-registration States, 1900–1902 to 1919–21, and United States, 1929–31 to 2000—Con.**

[Alaska and Hawaii included beginning in 1959. For decennial periods prior to 1929–31, data are for groups of registration States as follows: 1900–1902 and 1909–11, 10 States and the District of Columbia; 1919–21, 34 States and the District of Columbia. Beginning 1970 excludes deaths of nonresidents of the United States; see Technical Notes]

Age, race, and sex	Number of survivors out of 100,000 born alive ( <i>l<sub>x</sub></i> )										
	2000	1989–91	1979–81	1969–71	1959–61	1949–51	1939–41	1929–31	1919–21	1909–11	1900–1902

<sup>1</sup>For 1939–41 and 1949–51, data shown are for the entire nonwhite population. During these periods, life tables were not constructed for the black population. See Technical Notes.

**Table 12. Estimated life expectancy at birth in years, by race and sex: Death-registration States, 1900–28, and United States, 1929–2000**

[For selected years, life table values shown are estimates; see Technical Notes. Beginning 1970 excludes deaths of nonresidents of the United States; see Technical Notes]

Area and year	All races			White			Black <sup>4</sup>		
	Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
United States <sup>1</sup>									
2000	76.9	74.1	79.5	77.4	74.8	80.0	71.7	68.2	74.9
1999	76.7	73.9	79.4	77.3	74.6	79.9	71.4	67.8	74.7

<sup>1</sup>Alaska included in 1959 and Hawaii in 1960.<sup>2</sup>Deaths based on a 50-percent sample.<sup>3</sup>Figures by race exclude data for residents of New Jersey; see Technical Notes.<sup>4</sup>Prior to 1970, data for the black population are not available. Data shown for 1900–1969 are for the nonwhite population. See Technical Notes.

## Technical Notes

*The life table program*—Three series of complete life tables are prepared by the National Center for Health Statistics (NCHS) for the U.S. population—decennial, annual preliminary, and annual final. The U.S. decennial life tables are based on decennial census data and deaths for a 3-year period around the census year. Preliminary life tables are based on a substantial sample (approximately 90 percent) of death records. Estimates of life expectancy from the preliminary series are published annually. The annual final life tables (referred to in this section as “annual life tables”) are based on a complete count of all reported deaths.

Available since 1945, the annual life tables are based on deaths occurring during the calendar year and on midyear postcensal population estimates provided by the U.S. Census Bureau. From 1945 to 1996, the annual life tables were abridged life tables and were constructed by reference to a standard table (4). Beginning with 1997 mortality data, complete life tables are constructed using a new methodology (5,6). Also for 1997, life expectancy and other life table values were shown for ages 85 to 100 years for the first time as part of the annual U.S. life tables. Previously, the annual life tables were closed at age 85. Extension of the oldest age interval was implemented by NCHS for several reasons: survival in the United States is such that approximately one-third of the population survives beyond age 85; improvements have occurred in age reporting at older ages; and high-quality old-age mortality data are available from the Medicare program.

*Geographic coverage*—The geographic areas covered in life tables before 1929–31 were limited to the death-registration areas. Life tables for 1900–1902 and 1909–11 were constructed using mortality data from the 1900 death-registration States (10 States and the District of Columbia) and for 1919–21 from the 1920 death-registration States (34 States and the District of Columbia). The tables for 1929–31 through 1958 cover the coterminous United States. Decennial life table values for the 3-year period 1959–61 were derived from data that include both Alaska and Hawaii for each year (tables 10 and 11). Data for each year shown in table 12 include Alaska beginning in 1959 and Hawaii beginning in 1960. However, it is not believed that the inclusion of these two States materially affects life table values.

*Revised life table values, 1961–89*—Life table values for 1960–69, 1970–79, and 1980–89 were constructed using the U.S. decennial life tables for 1959–61, 1969–71, and 1979–81, respectively, as the standard tables. The life table values for years prior to 1989 appearing in this publication are based on revised intercensal estimates of the populations for those years. As a result, the life table values for these years may differ from the life table values for those years published in *Vital Statistics of the United States* for 1989 and earlier years. Life table values for 1991 and later are based on postcensal population estimates and will be recalculated when intercensal estimates become available.

*New Jersey data, 1962–64*—The life tables for 1962 and 1963 for the six population groups involving race do not include data from New Jersey, which omitted the item on race from its certificates of live birth, death, and fetal death in use at the beginning of 1962. The item was restored during the latter part of 1962. However, the certificate revision without this item was used for most of 1962 as well as for 1963. For computing vital rates, populations by age, race, and sex (excluding New Jersey) were estimated to obtain comparable denominators. Approximately 7 percent of the New Jersey death records for 1964 did not

contain the race designation. When the records were being electronically processed for this State, the “race not stated” deaths were proportionally allocated to white or to black.

*Nonresidents*—Beginning in 1970, the deaths of nonresidents of the United States have been excluded from the life table statistics.

*Estimation of life table functions*—For some years, it was necessary to estimate life table functions for some race-sex groups. In tables 10 and 11, figures for the black population during the periods 1949–51 and 1959–61 were estimated using figures for the nonwhite population. Life table functions were also missing in tables 10 and 11 for race-sex groups for the periods from 1900–1902 to 1939–41. Figures were missing for the following groups:

Years	Race and sex
1900–1902 . . . . .	Total white, total black
1909–11 . . . . .	Total white, total black
1919–21 . . . . .	Total, male, female, total white, total black
1929–31 . . . . .	Total, male, female, total white, total black

These figures were estimated by weighted averages using population distributions as the weights. For example, life expectancy at age 20 years for the total black population was estimated by a weighted average of black male and black female life expectancies at age 20, using as weights the population distribution by sex of the black population age 20 years.

Annual life tables were initiated in 1945 for white males, white females, all other males, and all other females. The figures in table 12 by race and sex for the following years were estimated using a procedure other than the abridged life table methodology (12).

Years	Race and sex
1900–45 . . . . .	Total
1900–47 . . . . .	Male
1900–47 . . . . .	Female
1900–50 . . . . .	White
1900–44 . . . . .	White male
1900–44 . . . . .	White female

Annual life table functions were not calculated for the black population prior to 1970. In table 12, life expectancy for the black population for years prior to 1970 is estimated using figures for the total nonwhite population.

*Population bases for computing life tables*—The population used for computing life table values shown in this section (furnished by the U.S. Census Bureau) represents the resident population of the United States. The age-specific populations used for computing the 2000 life table values are based on the July 1, 2000, population estimates that are consistent with the 1990 census (13). The 1990 census counts by race and age were modified. Race was modified to be consistent with the Office of Management and Budget categories and historical categories for mortality data. The modification procedures for race and age are described in a census report (14).

Detailed populations from the 2000 census were not available when this report was prepared. A comparison of summary 2000 census results and the estimates for 2000 used in this report indicates differences for some population groups. Differences between the 2000 enumerated population and the population estimates for 2000 used in this report could result in the underestimation or overestimation of life expectancy. When the necessary population estimates based on the

2000 census become available, life expectancy and other life table estimates will be recalculated and presented in an upcoming report. Meanwhile, considerable caution should be used in interpreting the statistics presented in this report.

**Medicare data**—Death rates at the oldest ages based on Medicare data are known to be more accurate than those based on vital statistics and census data. Consequently,  $q_x$  values calculated for ages 85 to 99 years are based on Medicare data prepared by the Health Care Financing Administration (HCFA). Medicare data were limited to the group insured for hospital insurance as age reporting is considered best among this group (6,10,11). For the 2000 life tables, 1997 Medicare data were used as 2000 data were not available in time for the preparation of this report.

**Methodology**

A more detailed treatment of the methodology used to calculate these life tables is contained in a separate report (5). Calculation of the complete life table is derived from the probability of death ( $q_x$ ), which depends on the number of deaths ( $D_x$ ) and the midyear population ( $P_x$ ) for each single year of age ( $x$ ) observed during the calendar year of interest.

**Adjustment for deaths for which age was not reported**—An adjustment must be made to account for the small proportion of deaths each year for which age is not reported. The data are aggregated into 5-year age groups for those age 5 years and over and into single years of age for those under 5 years. The number of deaths in each age category is adjusted proportionally to account for those with not-stated ages. The following factor is used to make the adjustment. This factor ( $F$ ) is calculated for each race-sex group for which life tables are constructed.

$$F = \frac{D}{D^a} \tag{1}$$

where  $D$  is the total number of deaths and  $D^a$  is the total number of deaths for which age is stated.  $F$  is then applied by multiplying it times the number of deaths in each age group. Table I shows values for  $F$  by race and sex used to adjust the 2000 mortality data.

**Interpolation of  $P_x$  and  $D_x$** —Anomalies, both random and those associated with reporting age at death, can be problematic when using vital statistics and census data by single years of age to estimate the probability of death (1). Graduation techniques are often used to eliminate these anomalies and to derive a smooth curve by age. Beer's

**Table I. Values for  $F$  used to adjust for not-stated age based on 2000 mortality data**

Race and sex	Total deaths	Total deaths for which age was not stated	$F$
Total . . . . .	2,403,351	356	1.00014815

ordinary minimized fifth difference formula is used to obtain smoothed values of  $P_x$  and  $D_x$  (see reference 5 for details on the application of Beer's method).

**Calculation of  $q_0$ — $q_0$**  is calculated by using a birth cohort method employing a separation factor ( $f$ ) defined as the proportion of infant deaths in year  $t$  occurring to infants born in the previous year ( $t-1$ ).  $f$  can be calculated by categorizing infant deaths by date of birth. The probability of death in the first year is calculated as

$$q_0 = \frac{D_0(1-f)}{B^t} + \frac{D_0 f}{B^{t-1}} \tag{2}$$

where  $D_0$  is the number of infant deaths adjusted for not-reported age, and  $B^t$  and  $B^{t-1}$  are the numbers of births in years  $t$  and  $t-1$ , respectively. Table II shows separation factors and numbers of births by race and sex for 1999–2000.

**Calculation of  $q_x$  for ages 1–84**— $q_x$  is calculated assuming that  $l_x$  (number of survivors at exact age  $x$  in the life table population) declines linearly between  $x$  and  $x+1$ , i.e., that deaths between exact age  $x$  and  $x+1$  occur on average at age  $x+1/2$ . This simplification is generally considered acceptable when age intervals are 1 year of age in length (1). Under this assumption,  $l_x = L_x + 1/2 d_x$  where  $L_x$  is the average life table population at risk of dying between ages  $x$  and  $x+1$  and  $d_x$  is the number of deaths occurring between age  $x$  and  $x+1$ .  $q_x$  is then

$$q_x = \frac{d_x}{l_x} = \frac{d_x}{L_x + \frac{1}{2} d_x}$$

One can make the same assumption for the observed population, i.e., that the observed population aged  $x$  at risk of dying at the beginning of the year ( $N_x$ ) declines linearly between ages  $x$  and  $x+1$ . Under this assumption,  $N_x = P_x + 1/2 D_x$  where  $P_x$  is the midyear population or average observed population at risk of dying between ages  $x$  and  $x+1$  and  $D_x$  is the observed number of deaths occurring between ages  $x$  and  $x+1$ .  $q_x$  is calculated as

$$q_x = \frac{D_x}{N_x} = \frac{D_x}{P_x + \frac{1}{2} D_x} \tag{3}$$

For  $x = 1$  to 4,  $D_x$  is the observed number of deaths adjusted for not-stated age and  $P_x$  is obtained by Beer's interpolation formula. For  $x = 5$  to 84, both  $D_x$  and  $P_x$  are obtained by interpolation (5).

**Use of Medicare data at ages 85 to 99 years**—There is ample evidence that the rate of increase in  $q_x$  declines above age 85 (5,11,15–17). The change in  $q_x$  for ages over 85 years can be expressed using the formula

$$q_x = q_{x-1} \cdot e^{k_x} \tag{4}$$

where  $k_x$  denotes the age-specific rate of mortality change with age (11,16). Solving for  $k_x$  gives

$$k_x = \ln(q_x) - \ln(q_{x-1}) \tag{5}$$

Values for  $k_x$  are then obtained from the Medicare data. Table III shows values for  $k$  by age, race, and sex based on 1997 Medicare data. These data show clearly a declining rate of increase in  $q_x$  above age 85. These  $k_x$  values are then used to obtain  $q_x$  values for ages 85 to 99 using equation 4. This method allows for flexibility in cases where the Medicare data are not available in a timely fashion. In these cases, Medicare data for the previous year can be used to calculate  $k_x$  values. Finally,  ${}_∞q_{100}$  is set equal to 1.0 since all will die at some point in this open-ended age interval. Once  $q_x$  is obtained for each

single year of age, the other life table functions may be easily calculated.

**Survivor function ( $l_x$ )**—The life table radix,  $l_0$ , is set at 100,000. For ages greater than 0, the number of survivors remaining at exact age  $x$  is calculated as

$$l_x = l_{x-1} (1 - q_{x-1}) \quad [6]$$

**Decrement function ( $d_x$ )**—The number of deaths occurring between age  $x$  and  $x + 1$  is calculated from the survivor function.

$$d_x = l_x - l_{x+1} = l_x q_x \quad [7]$$

Note that  ${}_{\infty}d_{100} = {}_{\infty}l_{100}$  since  ${}_{\infty}q_{100} = 1.0$ .

**Person-years lived ( $L_x$ )**—Person-years lived for ages 1 to 99 years is calculated assuming that the survivor function declines linearly between age  $x$  and  $x + 1$ . This gives the formula

$$L_x = \frac{1}{2} (l_x + l_{x+1}) = l_x - \frac{1}{2} d_x \quad [8]$$

For  $x = 0$ , the separation factor  $f$  is used to calculate  $L_0$ .

$$L_0 = f l_0 + (1 - f) l_1$$

${}_{\infty}L_{100}$  is calculated by surviving the life table cohort from age 100 using equations 4, 5, and 6 until  $L_x$  at these ages is essentially zero (somewhere between ages 110 and 120).  $q_x$  for these ages can be

extrapolated from the Medicare data using equation 4. However,  $k_x$  values must be estimated for these ages.  $k_x$  can be modeled as a linear function of age

$$k_x = k_{85} + (x - 85)s \quad [9]$$

where  $s$  is the slope of the change in  $k_x$  by age and  $k_{85}$  is calculated as  $[\ln(q_{88}/q_{81})]/7$  in order to minimize the effects of random fluctuations (11,17).  $s$  can be obtained by treating equation 9 as a linear regression model. Calculated values for  $s$  are shown in table IV. The predicted values for  $k_x$  are then used to calculate  $q_x$  above age 100 using equation 4. The corresponding  $L_x$  values for ages 100 years and over are then summed to give  ${}_{\infty}L_{100}$ .

**Person-years lived at and above age  $x$  ( $T_x$ )**— $T_x$  is calculated by summing  $L_x$  values at and above age  $x$ .

$$T_x = \sum_{t=0}^{\infty} L_{x+t} \quad [10]$$

**Life expectancy at age  $x$  ( $e_x$ )**—Life expectancy at exact age  $x$  is calculated as

$$e_x = \frac{T_x}{l_x} \quad [11]$$

**Abridging the complete life table**

An abridged or collapsed version of the complete life table can be easily calculated in which life table functions are shown for 5-year rather than single-year age intervals. It is often desirable to summarize the life table and save space when publishing life table data by single years of age (18). The abridgement of the complete life table is simplified by an important property of three of the six life table functions. The  $l_x$ ,  $T_x$ , and  $e_x$  functions describe exact age  $x$ , i.e., the beginning of the age interval  $x$  to  $x+n$  ( $n$  denotes the length of the age interval—for 5-year age intervals  $n=5$ ). Life expectancy at age 20 ( $e_{20}$ ), for example, has the same value regardless of whether the

age interval is 20–21 years or 20–25 years. Thus, the values  $l_x$ ,  $T_x$ , and  $e_x$  can be extracted at 5-year intervals from the complete life table and placed into the abridged life table (compare  $l_x$ ,  $T_x$ , and  $e_x$  in table V with the same functions in table 1). It is also illustrative to compare values for  $e_x$  and  $l_x$  in tables A and B with their corresponding values presented in tables 1–9. The  $q_x$ ,  $d_x$ , and  $L_x$  functions, in contrast, describe the age interval  $x$  to  $x+n$ . In fact, for abridged life tables, the notation for these functions is different ( ${}_nq_x$ ,  ${}_nd_x$ , and  ${}_nL_x$ ). Thus,  ${}_5q_{20}$  is the probability of dying between ages 20 and 25 years and will obviously be somewhat larger than  $q_{20}$ , the probability of dying between ages 20 and 21 years. Taking this into account,  ${}_nq_x$ ,  ${}_nd_x$ , and  ${}_nL_x$  must be recalculated in the abridged life table. It is simplest to begin with  ${}_nd_x$ . The calculations are made for all but the final age interval as follows:

$${}_nd_x = l_x - l_{x+n}$$

$${}_nq_x = \frac{{}_nd_x}{l_x}$$

$${}_nL_x = T_x - T_{x+n}$$

Note that for the open-ended interval, ages 100 and over:  ${}_{\infty}d_{100} = l_{100}$ ,  ${}_{\infty}q_{100} = 1.0$ , and  ${}_{\infty}L_{100} = T_{100}$ . Table V shows each of the life table functions for the 2000 U.S. total population abridged from table 1.
